Abstract

Coq's consistency — and the consistency of constructive type theories in general — crucially depends on all recursive functions being terminating. Technically, in Coq, this is ensured by a so-called guard checker, which is part of Coq's kernel and ensures that fixpoints defined on inductive types are structurally recursive. Coq's guard checker has been first implemented in the 1990s by Christine Paulin-Mohring, but was subsequently extended, adapted, and fixed by several contributors. As a result, there is no exact, abstract specification of it, meaning for instance that formal proofs about it are out of reach. We propose a talk on our ongoing work-in-progress project to synthesise a specification of Coq's guard checker as a guard condition predicate defined in Coq itself on top of the MetaCoq project. We hope that our project will benefit the users of Coq by providing an accurate and transparent description, as well as lay the foundations for future improvements or even mechanised consistency proofs of Coq.

In Coq, one can define inductive types which have parameters, be indexed, mutual, or nested. Common examples are natural numbers, lists (which have a parameter), vectors (which have indices), even/odd predicates (which are mutual), the accessibility predicate (which has nesting via a function type), and rose trees (which have nesting via inductive types). One can then define so-called fixpoints by structural recursion on elements of these inductive types. As an example here is a definition of the recursor on natural numbers as a fixpoint:

All of the mentioned features like mutuality and nesting introduce mostly orthogonal complexity in the definition of Coq's guard checker, which is defined in the kernel/inductive.ml file of Coq's code in about 1000 lines of OCaml code.

To illustrate how a guard checker is crucial for consistency, one can look at the following two non-terminating fixpoints

They allow proofs of False as boom 0 and exploiting the contradictory property of inf 1 = S (inf 1).

History of the guard condition

In the 1990s, Frank Pfenning and Christine Paulin-Mohring introduced inductive types in the calculus of constructions [1] along with a guard condition for fixpoints [2]. In 2012, Pierre Boutillier relaxed the guard checker via β - ι commutative cuts [3]. In 2014, Maxime Dénès restricted the guard checker to forbid an unwanted proof that propositional extensionality does not hold in Coq [4]. In 2022, Hugo Herbelin restricted the guard checker to ensure strong normalisation rather than just weak normal-

isation, which is a behaviour that seems to be more in line with the intuition of users [5]. In 2024, Herbelin introduced a relaxation, allowing simpler implementation of nested recursive functions [6]. Furthermore, changes to the guard condition keep being proposed, see e.g. [7] and [8].

MetaCoq: a formalisation of Coq in Coq

Two central parts of the MetaCoq project [9] are a formalisation of Coq's type theory in Coq [10] and, on top of that, verified implementations of a type checker [11] and several extraction functions to OCaml [10]. The formalisation of type-theory faithfully captures typing rules of Coq in an inductive predicate, and is parameterised in a guard checker function which is requried to fulfil some basic properties such as being stable under reduction and substitution. Based on this formalisation, crucial properties such as subject reduction (types are preserved by reduction) and canonicity (normal forms of inductive types start with a constructor) are proved [11].

The verified type checker axiomatically assumes that reduction in the system is strongly normalising. The strong normalisation assumption can also be used to prove consistency, because any proof of False would have a normal form using strong normalisation, which would have the same type using subject reduction, and would start with a constructor of the inductive type False using canonicity – which is a contradiction, because False has no constructors.

Towards a formalised guard condition

In the talk, we will report on the first step of our project, namely to synthesise a guard condition predicate from the current OCaml implementation of the guard checker. This predicate will work similarly to the typing predicate in MetaCoq, i.e. talk about the syntax of Coq as specified in MetaCoq. This specification can be an inductive predicate, meaning it does not have to be obviously decidable.

Towards a verified guard checker

As a second step of the project, we want to implement a guard checker function deciding the guard condition predicate. This function will have to use MetaCoq's verified implementation of reduction, meaning it will have to rely on the strong normalisation axiom. Technically, a substantial challenge will lie in proving that the definition of this guard checker function, defined in Coq and working on syntax as specified by MetaCoq, is terminating. That this function indeed correctly computes the guard condition predicate can either be immediately proved by using dependent types and a correct-by-construction guard checker function, or in a separate additional step. Note that technically, proving the soundness of the function suffices, i.e. that whenever the function accepts a term, the guard condition predicate holds.

Towards normalisation proofs

Having a formal description of the guard condition now allows relative normalisation proofs of Coq's type theory in Coq. Namely, it then is feasible to define a simpler, more natural, and more modular variant of guard condition and show that Coq's type theory with the current implementation of the guard condition can be interpreted in this simpler theory. This would result in a relative normalisation proof, meaning that Coq's type theory is normalising (and thus consistent) if the simpler system is normalising. In particular, this means that the trust in Coq's consistency could be moved to trusting that such a simpler theory is terminating. In the long term future, it then even could be possible to *prove* termination of Coq's type theory (for a restricted number of universes to get around Gödel incompleteness issues) by reducing it in many steps to an extension of the currently also ongoing formalisation of MLTT in Coq [12].
